**SECTION 1 - SCOPE AND PURPOSE**

This specification describes the program functions of the IP Remote Driver, the software to exercise a vendor's Internet Protocol (IP) implementation (HUT) for MIL-STD-1777. Because it runs on the vendor's host rather than in the Protocol Test System, the software is called a Remote Driver (RD). An IP host/Remote Driver must also be supplied for gateway IP testing.

## SECTION 2 - THE PROTOCOL TEST SYSTEM

### 2.1 DESIGN

The Protocol Test System (PTS) exercises an IUT performing peer protocol exchanges with a reference implementation at the Protocol Test System site. A driver controls each peer protocol through its upper level interface. To generate reproducible results, a script controls each driver.

The major components of the Protocol Test System are:

- o Central Driver--to coordinate and monitor protocol testing;
- o Remote Driver--to exercise the IP IUT
- o Laboratory Slave Driver--to exercise the IP Reference implementation, record IP datagrams exchanged over the test connections, and provide communication links with the Central Driver.

The Central Driver, which coordinates and monitors protocol testing, analyzes the input it receives from the Laboratory Slave Driver to determine the success or failure of each test.

### 2.2 FUNCTIONS

The IP RD makes it possible for the Central Driver to interact with the IP IUT. The RD establishes a connection through its local IP and waits for datagrams from the Laboratory Slave Driver's (LSD) address. When such a datagram arrives, the RD parses the data area in a search for commands that instruct it to form a datagram to the LSD. If unable to respond as directed, the RD notifies the LSD by means of a mutually known set of messages that are described in Section 4.2. All data received from the IUT are forwarded to the Central Driver.

### SECTION 3 - ENVIRONMENT

#### 3.1 SUPPORT SOFTWARE

The Internet Protocol Remote Driver may reside on any computer that supports the Military Standard IP. In addition, the IP RD may be written in any language and may have any type of system support.

#### 3.2 INTERFACES

##### 3.2.1 Upper Layer Protocol to Internet Protocol.

Table 1 shows the minimum information that the IP RD must be able to send to the IP IUT (Internet Protocol Implementation Under Test).

PARAMETER	DEFINITION
Source Address	- Address to be placed in source field of IP packet header.
Destination Address	- Address to be placed in destination field of IP packet header.
Protocol	- Upper Layer Protocol Number.
Type of Service	- Values indicating: Precedence Delay Throughput Reliability.
Don't Fragment	- Indication to set the IP don't fragment option.
Time-to-Live	- Indication to set the IP packet's useful lifetime.
Length	- Indication of IP packet's desired length.
Option	- Option field requested to be placed in IP packet header
Data	- Data for IP to pack into data field.
Security level	- Security level for security option requested to be placed in IP header
Accreditation Authority	- Accreditation authority to be placed with preceding security level in IP header

TABLE 1. IP Parameters

### 3.2.2 Internet Protocol to Upper Layer Protocol.

Table 2 shows the minimum information from the IP IUT that the IP RD must be able to recognize.

PARAMETER	DEFINITION
Source Address	- Address from source field of IP packet header.
Destination Address	- Address from destination field of IP packet header.
Protocol	- Upper Layer Protocol Number.
Type of Service	- Values indicating: Precedence Delay Throughput Reliability.
Length	- Length of IP packet.
Data	- Data from IP data field.
Error	- Error indication from IP.

**TABLE 2. IP Responses**

## SECTION 4 - DATAGRAM PRESENTATION

Each datagram sent to the IUT consists of a series of independent commands. Except for **ident**, a command may appear in any position: The **ident** command will always be first in the sequence. Figure 2 shows a typical datagram that will be sent to the IUT.

**ident = 12345 proto = 255 prec = 7 ipttl = 25 datalen = 128**

**FIGURE 1. IP RD Command String**

### 4.1 COMMAND COMPONENTS

Figure 3 shows the syntax of most IP Remote Driver commands, which consist of a keyword and a decimal value.

**keyword<space>=<space>value<space>**

**FIGURE 2. IP RD Command Syntax**

The only exceptions are the **end** and **option** commands. The **end** command consists of the "end" keyword by itself. The **option** command consists of the "option" keyword immediately followed by up to 40 bytes that occupy the remainder of the data field.

All bytes in the data field are ASCII characters except for the bytes that follow an "option" keyword.

4.1.1 Keywords.

Table 3 lists the keywords for Remote Drivers.

KEYWORDS	SEMANTICS
source	- Use source address that follows.*
dest	- Send message to address that follows.*
proto	- Use protocol that follows.
prec	- Use precedence that follows.
reliab	- Turn on reliability bit.
delay	- Turn on delay bit.
throu	- Turn on throughput bit.
ident	- Use identification that follows or any other value permitted by the Military Standard.
dontfrag	- Turn on don't fragment flag.
ipttl	- Use time-to-live that follows.
datalen	- Send back a message of the following length.
option	- Use the following option string to send this message.*
security	- Send back a message containing a security option set with this security level and the accreditation provided in a companion command.
accreditation	- Use this accreditation with the security level provided in a companion command.
end	- End test.

TABLE 3. Remote Driver Keywords

\*Note: All addresses are given in network octal.

#### 4.1.2 Values.

Each keyword can be assigned a range of values. Table 4 lists each keyword, its corresponding range of values, and the value that should be set as the default.

KEYWORD	RANGE OF VALUES	DEFAULT
source	---	IUT's address
dest	---	LSD's address
proto	0 - 255	255
prec	0 - 7	0
reliab	0 - 1	0
delay	0 - 1	0
throu	0 - 1	0
ident	0 - 65535	1
dontfrag	0 - 1	0
ipttl	0 - 255	15
datalen	0 - 65535	length of received datagram's data field
security	0 - 65535	0
accreditation	0 - 65535	0

TABLE 4. Remote Driver Keywords and Values

## 4.2 RESPONSE COMPONENTS

Normally, the IP RD ensures that the header information is correctly set and that the data field is the requested length. The data field should be created by replicating or truncating the command string until the requested length is obtained.

Table 5 lists appropriate responses for two inoperative conditions. If the IUT does not implement one of the requested commands, it should place the **ident** command followed by the string "notimpl" in the response datagram's data field. If the IUT rejects the response datagram, it should send another datagram with the **ident** command followed by the string "error" in the datagram's data field.

RESPONSE	INSTRUCTIONS
error	- If the IP IUT does not accept a datagram, send back response to Central Test Driver.
notimpl	- If the IP IUT does not implement a command, send back response to Central Test Driver.

**TABLE 5. Remote Driver Responses**

## SECTION 5 - DESIGN DETAILS

The following sections explain the initialization and operation of a Remote Driver.

### 5.1 CONNECTION ESTABLISHMENT

At runtime, the RD should perform any internal initialization necessary, and then wait at an address obtainable from the Protocol Test System testing facility for a connection from the Laboratory Slave Driver. This address is always an address on the same proximate net as the Protocol Test System testing facility.

### 5.2 COMMAND RECEPTION

Each RD must accept datagrams of up to 1024 bytes, with a protocol number of 255. Note the Central Test Authority can change the protocol number to something else if necessary. The RD must recognize all the keywords listed in Table 3, and may notify the Laboratory Slave Driver of any it does not implement. (See Section 4.2.)

For the accepted commands, the RD applies all implementation details required to ensure that the semantics of the commands are executed. This execution normally will involve creating an IP packet with the appropriate settings in the header and having the IP IUT send the packet to the LSD. The data portion of the IP packet should be the original command string reproduced as often as necessary to satisfy any packet length request in the original command string.

### 5.3 PACKET TRANSMISSION

After the RD has created the test IP packet according to the instructions of the command string, it attempts to send the packet back to the Laboratory Slave Driver via the IP IUT. If the IP IUT rejects the packet, the RD sends an error response packet instead. The IP header identification number of the error response packet should be set as indicated by the **ident** command. All other IP header fields should be set to their Table 4 default values. The data field should contain the **ident** command, followed by the string "error". (Note: Sending an error response packet does not necessarily constitute an error in the IP IUT.)

### 5.4 CONNECTION TERMINATION

Upon receipt of the command **end** (or upon a fatal error in the local implementation), the Remote Driver closes the IP connection with the Laboratory Slave Driver. No response datagram is expected or permitted.

**APPENDIX A - References**

"Military Standard Internet Protocol," MIL-STD-1777 (12 August 1983)

Internet Protocol Programmers and Users Manual, SDC TM-WD-8801/017/00

**APPENDIX B - Glossary**

This list of terms and acronyms does not include item names or data codes.

ASCII	- American Standard Code for Information Interchange. A data communications code set.
CD	- Central Driver
IP	- Internet Protocol
IP RD	- Internet Protocol Remote Driver
LSD	- Laboratory Slave Driver
RD	- Remote Driver
ULP	- Upper Layer Protocol
Datagram	- A self-contained package of data carrying enough information to be routed from source to destination without reliance on earlier exchanges between source or destination and the transporting subnetwork.
Keyword	- A lowercase ASCII string with a defined meaning.

APPENDIX C - Program Logic

[ IP Remote Driver  
[ Brian Griffin  
[ 9/15/86  
[ This PDL represents an Internet Protocol Remote Driver  
[ for MIL-STD-1777 certification testing. It assumes that  
[ the IP header is used to pass most of parameters for the  
[ section 6 interaction primitives.  
[ MAJOR DATA STRUCTURES:  
[ FROM\_ULP           The response datagram molded by the Remote  
[                     Driver to be sent by the Implementation  
[                     Under Test.  
[ TO\_ULP             The datagram delivered by the IUT to the  
[                     Remote Driver and an error code.  
[ MINOR VARIABLES:  
[ DATA\_LENGTH       The amount of data requested to be sent  
[                     in the response datagram.  
[ DATA\_OFFSET       The offset within the datagram's data  
[                     field.  
[ OPTION\_OFFSET      The offset within the received datagram's  
[                     data field where 0 to 40 octets of the  
[                     requested response datagram's option  
[                     field can be found.  
[ TEST\_ID            The value of the identification to be  
[                     used for the response datagram. It may  
[                     be needed to send a possible error or  
[                     not implemented response datagram.  
[ NOTICE:  
[ This PDL may require some modification to work with the  
[ IP Implementation Under Test.
